Hohmann transfer

The cheapest two-burn move between circular orbits of radius r_1 and r_2. The first burn raises the far point of the orbit to r_2:

$$\Delta v_1 = \sqrt{\frac{\mu}{r_1}}\left(\sqrt{\frac{2r_2}{r_1 + r_2}} - 1\right)$$

Here μ = GM is the standard gravitational parameter of the central body.

The second burn

At r_2 the craft is slower than a circular orbit there, so it burns again:

$$\Delta v_2 = \sqrt{\frac{\mu}{r_2}}\left(1 - \sqrt{\frac{2r_1}{r_1 + r_2}}\right)$$

The total cost is $\Delta v = \Delta v_1 + \Delta v_2$.

Transfer time

The transfer is half an ellipse with semi-major axis a = (r_1 + r_2)/2, so by Kepler's third law:

$$t_H = \pi \sqrt{\frac{(r_1 + r_2)^3}{8\mu}}$$
